Primary Polyfluoroallylic Alcohols. Preparation and Isomerization into 2-Fluoroacrylic Acid Fluoride and 1-Fluoro Vinyl Ketones

T. Nguyen* and C. Wakselman

CNRS-CERCOA 2 & 8, rue Henri Dunant, 94320 Thiais, France

Received March 6, 1989

Alkyl and aryl 2-fluoroacrylic acid esters have been used as starting materials for number of coating agents, dental polymers,¹ and special glass.² These esters have been commonly prepared from 2-fluoroacrylic acid halides $\text{CH}_2=\text{CFCOX}$ ($\text{X} = \text{Cl}, \text{Br}, \text{F}$). The recent processes for having these intermediates involved the rearrangement

of an alkoxy cyclopropane³ (Scheme I) or the opening of an oxetane by a nucleophile⁴ (Scheme II).

These two reactions brought great improvements over the previous method which used as starting material the very toxic 2-fluoroacetic derivatives.⁵ The cyclopropane route needs nevertheless several steps, and the oxetane⁶ is also toxic. Another possible way of obtaining 2-fluoroacrylic acid halides should be a rearrangement of 2-fluoroacrylic alcohols $\text{CH}_2=\text{CFCH}_2\text{OH}$ if these alcohols are available. The allylic rearrangements were already performed on secondary and tertiary fluoroallylic alcohols,⁷ but not on a primary alcohol. The reason was certainly an absence of a practical method of preparation of these alcohols. Therefore we were searching a convenient method of obtaining primary polyfluoroallylic alcohols.

A few years ago, we showed that 1-H perfluoroalkyl chains are transformed into fluorinated olefins by action of strong bases like lithium dialkylamides⁸ or organolithium reagents¹⁰ (Scheme III).

This conversion was observed with alcohols $\text{HCF}_2\text{CF}_2(\text{CF}_2)_n\text{CH}_2\text{OH}$ when n was equal to 2, 4, or 6. The vinyl intermediate 2 was not isolated. This fluorinated olefin, activated by the electron-withdrawing difluoromethylene group, was steadily attacked by the organolithium reagent. However, the case of the alcohol $\text{HCF}_2\text{CF}_2\text{CH}_2\text{OH}$ 4 corresponding to n equal to zero, was not examined at that time. Recently we were asking ourselves what could be the reactivity of the intermediate olefin 5 which is not activated by an adjacent electronegative group. Is it possible to stop the condensation at the intermediate step 5 in order to get the allylic alcohol 7 after hydrolysis? (See Scheme IV.)

We report here that this transformation can be performed under controlled conditions of temperature and reaction time. Addition of methylthium to the alcohol 4 in diethyl ether at 0 °C and stirring during 5 h at room temperature led, after hydrolysis, to a mixture containing 74% of 7, 16% of 8, and 10% of the starting material 4 as shown by an NMR analysis. If the condensation is allowed to go to completion when the addition is performed at room temperature the substituted allylic alcohol 8 can

be obtained with 56% yield. Similar transformation of alcohol 9 into alcohol 10 has been also observed.

Since alcohols 4 and 9 were easily available,^{11,12} this process for having polyfluoroallylic alcohols appeared very attractive. One valuable development was the allylic rearrangement which occurs steadily in acidic medium. From alcohol 7, 2-fluoroacrylic acid fluoride 11 was obtained in good yield. Likewise was for alcohol 10. In the case of 10, the superior ability of chlorine over fluorine as leaving atom was obvious. Allylic rearrangement occurred equally with alcohols 8; 1-fluorovinyl ketones 12 resulted (Scheme V).

Ketones of this type were prepared by a carbene route¹³ or by organometallic condensations.^{14,15} The present process was comparatively straightforward.

In conclusion, we are reporting a simple way to prepare primary polyfluoroallylic alcohols 7, 8, and 10, which use the easily accessible 3-hydroxypropylfluoropropanol 4 and 9 as starting materials. We have performed the allylic rearrangement of alcohols 7 and 10 into 2-fluoroacrylic acid fluoride 11, a valuable synthon in the preparation of 2-fluoroacrylic polymers. By extension of the method to alcohols 8 which were obtained by the same process, 1-fluorovinyl ketones 12 were prepared.

Experimental Section

¹H and ¹⁹F NMR spectra were recorded on a Varian EM360L instrument, and chemical shifts were reported in ppm from TMS in δ scale for ¹H, from CCl₄ in δ scale for ¹⁹F. IR spectra were recorded on a Perkin-Elmer 1420 spectrometer. Elemental analyses were carried out in the Laboratoire Central d'Analyse de CNRS (Lyon). 3-H tetrafluoropropanol was purchased from TCI Tokyo, Japan, alkyllithium from Janasen Chimica Beers Belgium, and chlorotrifluoroethylene from Matheson Ovale Belgium.

Trifluoroallylic Alcohol, 7. To a solution of alcohol 4 (20 g, 151 mmol) in 20 mL of anhydrous diethyl ether was added dropwise, at 0 °C, 320 mmol of methylolithium (1.2 M solution in ether); over a period of 1 h, the temperature was allowed to reach room temperature. Stirring was continued for 5 h afterward the reaction flask was again cooled to 0 °C. Concentrated HCl

(18 mL) was carefully added, and the pH was adjusted to 6 or 7. The solution was left for the night, and then the organic phase was separated, washed, and dried over magnesium sulfate. Diethyl ether was distilled off, leaving a crude oil which was flash distilled to give a clear liquid (bp 80 °C, 100 Torr; 17 g). By introduction of a known quantity of CFCl_3 in a sample of the distillate, one can evaluate the ratio of different fluorinated compounds obtained as in the following: 74% of 7, 16% of 8, and 10% of 4. Purified alcohol 7 was obtained by a second distillation in the presence of hydroquinone (bp 98 °C, 12.5 g, yield 74%). The ¹H NMR and ¹⁹F NMR data of 7 are found in Table I. Anal. Calcd for $\text{C}_{10}\text{H}_{12}\text{F}_2\text{O}$: C, 52.17; H, 2.70. Found: C, 52.34; H, 2.75.

3-Chloro-2,3-difluoroallylic Alcohol, 10. The same process applied to a solution of alcohol 9, $\text{CHClCF}_2\text{CH}_2\text{OH}$ (10 g, 68.4 mmol), in 10 mL of anhydrous diethyl ether, and 127 mmol of methylolithium, gave a crude distillate (bp 90–95 °C, 125 Torr; 7.8 g) from which alcohol 10 (bp 116 °C; 5.7 g) was isolated as two isomers (*E/Z* equal to 45/55). Their ¹H NMR and ¹⁹F NMR data are found in Table I. IR (CCl₄): 3300 (OH), 1780 cm^{-1} (C=CF₂). Anal. Calcd for $\text{C}_3\text{H}_3\text{ClF}_2\text{O}$: C, 28.04; H, 2.35. Found: C, 28.18; H, 2.48.

3-Methyl-2,3-difluoroallylic Alcohol, 8. To a solution of 10 g (76 mmol) of alcohol 4 in 30 mL of diethyl ether was added dropwise with stirring 220 mmol of methylolithium. The stirring was continued overnight at room temperature. The solution was neutralized carefully and worked up as in the preparation of 7. A fractionation of the crude distillate gave 7 (1 g, 9 mmol) and 8 (4.6 g, 42.7 mmol, yield 56%) as a mixture of two isomers (*E/Z* equal to 80/20). We cannot separate these isomers by VPC through a column of SE30 heated to 130 °C. The ¹H NMR and ¹⁹F NMR data of these isomers are found in Table I. IR (CCl₄): 3300, 3230 (OH), 1740, 1710 cm^{-1} (C=CF₂). Anal. Calcd for $\text{C}_4\text{H}_6\text{F}_2\text{O}$: C, 44.48; H, 5.8; F, 35.18. Found: C, 44.77; H, 5.61; F, 34.12.

3-Butyl-2,3-difluoroallylic Alcohol, 8'. Similarly, a solution of 7 g (53 mmol) of alcohol 4, 70 mL of diethyl ether, and 180 mmol of butyllithium (1.2 M solution in hexane) gave 6.8 g of crude distillate, bp 70–80 °C (16 Torr), from which 5.4 g (36 mmol) of 8' were isolated, yield 66%. The isomers *E* and *Z*, bp 178 °C, and *Z*, bp 188 °C, were separated by VPC through a column of SE 30 heated to 180 °C. The ratio *E/Z* was 77/23. The ¹H NMR and ¹⁹F NMR data of these isomers are found in Table I. IR (CCl₄): 3300, 3230 (OH), 1739 cm^{-1} (C=CF₂). Anal. Calcd for $\text{C}_7\text{H}_{12}\text{F}_2\text{O}$: C, 56.05; H, 8.06; F, 25.33. Found: C, 56.17; H, 8.13; F, 24.82; (Z): C, 55.87; H, 8.93.

2-Fluoroacryloyl Fluoride, 11. Into a distillation flask containing 10 mL of concentrated sulfuric acid was added dropwise with stirring 2.6 g (32 mmol) of alcohol 7. An exothermic reaction occurred. The volatile acryloyl fluoride 11 formed was distilled in vacuo (200 Torr) in a receiver cooled by a dry ice-acetone mixture. Obtained was 1.15 g (12.6 mmol), yield 55%.

Similarly, 4.5 g (35 mmol) of alcohol 10 gave 2.78 g (28 mmol) of 11. Yield 82%. The ¹H NMR and ¹⁹F NMR data of 11 were in Table I. Treated by a solution of phenol in CH_2Cl_2 , 11 gave the known phenyl 3-fluoroacrylate ester 2.

Fluorovinyl Methyl Ketone, 12. A mixture of 2.4 g (18.9 mmol) of alcohol 8, $\text{CH}_2\text{CF}=\text{CFCH}_2\text{OH}$, 10 mL of tetrachloroethane, 0.5 mL of concentrated sulfuric acid, and hydroquinone was heated for half an hour on an oil bath at ca. 100 °C; it was then distilled in vacuo to give a crude distillate, bp 60–80 °C (100 Torr), 7.2 g. It contains 14.5 mmol (evaluated by ¹⁹F NMR) of ketone 12, which was separated by a second distillation in the presence of hydroquinone at room temperature under 15 Torr. Yield 1.3 g, 78%. The ¹H NMR and ¹⁹F NMR spectra of 12 are in Table II. IR (CCl₄): 1730, 1710 (C=O), 1640 cm^{-1} (C=CF₂). These characteristics were in agreement with those given in the literature.¹³

1-Fluorovinyl *n*-Butyl Ketone, 12'. A mixture of 3.1 g (14 mmol) of alcohol 8', *E* and *Z* $\text{C}_4\text{H}_7\text{CF}=\text{CFCH}_2\text{OH}$, 5 mL of CH_2Cl_2 , 0.5 mL of concentrated sulfuric acid, and hydroquinone was heated for half an hour on an oil bath at ca. 100 °C and then distilled off in vacuo to give ketone 12', bp 75–80 °C (160 Torr), 1.2 g (8.6 mmol), yield 61%. The ¹H NMR and ¹⁹F NMR data of 12' are in Table II. IR (CCl₄): 1710 (C=O), 1640 cm^{-1} (C=CF₂). Anal. Calcd for $\text{C}_5\text{H}_9\text{FO}$: C, 64.67; H, 8.33. Found: C, 64.00; H, 8.60.

Functionalization of 1*H*-Perfluoroalkyl Chains

Claude Wakselman* and Thoa Nguyen

C.N.R.S.-C.E.R.C.O.A., rue Henri Dunant, 93420 Thiais, France

Received April 23, 1976

The terminal hydrogen of 1*H*-perfluoroalkyl chains is known to be extremely inert.¹ These compounds can only be halogenated² or oxidized³ by a radical mechanism at a very high temperature. They are not affected by concentrated potassium hydroxide at 100 °C; however, a slow hydrogen-deuterium exchange has been demonstrated in methanol.⁴

We describe here the mild ionic reaction of lithium dialkylamide on compound 1 yielding the amide 6. The most probable reaction pathway is as follows:

The lithium dialkylamide initially reacts as a strong base, abstracting a proton from the CHF_2 group, then as a nucleophile which adds readily on the fluorinated alkene 3. This attack occurs on the difluoromethylene group and yields the most stable anion 4. Carbanions 2 and 4 produce respectively the perfluoroalkene 3 and the fluorinated enamine 5, both by loss of F^- . This enamine 5 may be isolated in aprotic media. For instance, $\text{C}_6\text{H}_5\text{CH}_2\text{OCH}_2\text{CF}_2\text{CF}_2\text{CF}=\text{CFN}(\text{CH}_2\text{CH}_3)_2$ (5d) was enough stable to be recovered unchanged after 1 month at 0 °C; its ^{19}F NMR spectrum shows a *cis* configuration ($J_{\text{FF}} = 7$ Hz). Using the lithium reagent (1–2 molar equiv) we have found that the reaction needs 2 molar equiv to go to completion and not any olefin 3 could be detected during the reaction by ^{19}F NMR on the crude reaction medium.

Amide 6 can be obtained from 1*H*-perfluoroalkyl chains containing a variety of functional groups such as ether, ketal, amide, etc. This type of compounds is readily available by a radical addition on tetrafluoroethylene.⁵ The compounds with $\text{R}_f = -(\text{CF}_2)_n\text{CH}_2\text{OH}$ can be obtained commercially.⁶ The results obtained with various substrates, using 2 equiv of lithium diethylamide in diethyl ether, are listed in Table I.

Bifunctional fluorinated compounds are relatively rare synthetic intermediates.⁷ They are generally symmetrical. The functionalization of 1*H*-perfluoroalkyl chains by lithium dialkylamide constitutes a smooth access to symmetrical or unsymmetrical bifunctional fluorinated intermediates.

Experimental Section

^1H NMR spectra were recorded on a Perkin-Elmer R24 spectrometer with Me_4Si as internal standard. ^{19}F NMR spectra were recorded on a JEOL C-60HL spectrometer with CFCl_3 as external standard. Chemical shifts are given in parts per million. A downfield displacement is positive for proton, negative for fluorine. Coupling constants are in hertz. The s, d, t, q, m, usual abbreviations are used with the composite form dd, dt, dm, it, ddd which are doublet of doublets, doublet of triplets, doublet of multiplets, triplet of triplets, and doublet of doublets of doublets. IR spectra were obtained on a Perkin-Elmer 167 spectrometer. Mass spectra data were obtained on a ABI MS 30 spectrometer.

We thank Mr. Foulletier (PCUK)¹¹ for a sample of 1*H*-perfluorohexane 1a. 1*H*,5*H*-Perfluorohexane 1b was prepared according to the method of Brace.⁸ Compounds 1c and 1d were prepared starting from commercial (PCR)¹¹ 1*H*,1*H*,7*H*-dodecafluorooctanol and 1*H*,1*H*,8*H*-octafluoropentanol. The first alcohol was oxidized following Joyce procedure⁹ and the acid was transformed as usual in acid chloride, then in amide 1c. The second alcohol was transformed in ether 1d with benzyl bromide. Compound 1e was obtained by transesterification¹⁰ of 7*H*-dodecafluorooctanoic acid prepared according to the method of Brace.⁸ We thank Mr. M. Rubinstein for technical assistance and the D.G.R.S.T.¹¹ for financial support.

Preparation of *N,N*-Diethyl-2*H*-decafluorohexanamide Amide (6a). Into a 250-mL three-neck flask equipped with a mechanical stirrer, a condenser-drying tube system, and addition funnel fitted to provide an argon atmosphere was placed 5 g (15 mmol) of 1*H*-perfluorohexane in 30 mL of anhydrous diethyl ether. The flask was cooled at -10 °C with a CCl_4 -dry ice bath. With stirring, a white suspension of lithium diethylamide (prepared by addition of 3.5 g (48 mmol) of diethylamine in 100 mL of ether on 31 mmol of a butyllithium solution in pentane at 0 °C) was added dropwise. After stirring the mixture for 1 h, it was acidified with 30 mL of 20% HCl solution. The mixture was extracted with diethyl ether. The organic layer was dried over MgSO_4 and filtered, and the solvent was evaporated under reduced pressure. The residue was distilled under vacuum to give 3.5 g of 6a: bp 95–96 °C (12 mm); IR (neat) 1660 cm^{-1} (amide); ^1H NMR (CDCl_3) 3.45 (q, 4 H, $J = 7$ Hz), 1.2 (t, 6 H), 5.5 (ddd, 1 H, $J = 46, 16, 7$ Hz); ^{19}F NMR (CDCl_3) 79 (3 t, 3 F, $J = 11, 2$ Hz), 124 (m, 2 F), 121 (m, 2 F), 117 (dm, 1 F, $J = 250$ Hz), 121 (dm, 1 F), 194 (ddd, 1 F); mass spectrum *m/e* (rel intensity) 851 (M^+ , 67), 336 ($\text{M} - \text{CH}_3$, 56), 332 ($\text{M} - \text{F}$, 100), 322 ($\text{M} - \text{C}_2\text{H}_5$, 48).

Anal. Calcd for $\text{C}_{12}\text{H}_{14}\text{F}_{10}\text{NO}$: C, 34.15; H, 3.12; F, 54.10. Found: C, 34.06; H, 3.10; F, 54.23.

The same general procedure was used to prepare the other amides 6.

Received June 2, 1976

In a previous report,¹ we described a synthesis of 3,11-dimethyl-2-nonacosanone (1), an active component of the contact mating pheromone present in the cuticle of the female German cockroach (*Blattella germanica*). Recently, Ishii and co-workers,² who first isolated and synthesized this substance,² have identified a closely related second component, 29-hydroxy-3,11-dimethyl-2-nonacosanone (2).³ In connection with

studies on the behavioral responses of cockroaches to pheromones,⁴ we undertook and now describe a synthesis of 2 together with some preliminary bioassays.

As shown in Chart I, the benzyl ether (3) of 4-bromo-1-butanol was used to assemble the terminal hydroxy chain.

Chart I

This derivative was selected because of its greater stability and convenience for removal compared to the alternative tetrahydropyranyl ether and because its distinctive spectral features made it especially useful for monitoring subsequent steps. The preparation of 3 was achieved in 88% yield by the phase-transfer catalyzed reaction⁵ of 1,4-dibromobutane (5 equiv) with sodium benzyloxide. By alkylation with lithium acetylide (as the ethylenediamine complex), 3 was converted almost quantitatively into the acetylenic ether 4. Monoalkylation of 1,12-dibromododecane (3 equiv) with the lithium salt of 4 then provided the acetylenic bromo ether 5 in 84% yield.

In the next step, a Wittig reaction of 9-bromo-2-nonanol⁶ with the triphenylphosphorane derivative of 5 gave the olefinic bromo ether 6 as a mixture of *Z* and *E* isomers in 58% yield. Alkylation of 6 with ethyl 2-methylacetoacetate then furnished the required benzyloxy keto ester 7 in 91% yield. Finally, hydrogenation-hydrogenolysis of 7 gave the saturated hydroxy keto ester 8 (97% yield), mp 30–32 °C, which, when hydrolyzed and decarboxylated, afforded, in 71% yield from 8, the desired hydroxy ketone 2 as a mixture of diastereoisomers, mp 41.5–43 °C.

Bioassay by antennation^{1,2} showed that synthetic 2 readily evoked the characteristic preovulatory wing raising and 180°-turning response in isolated adult male German cockroaches. Male roaches isolated from their parent colonies were housed and tested in groups of five. In the tests their antennae were stroked intermittently (~10 s/min) with freshly ablated American cockroach (*Periplaneta americana*) antennae that had been dipped for 1–2 s into a carbon tetrachloride solution of the test substance and then allowed to dry.⁵ All tests were performed at 24–26 °C during a period of 2.5–4.0 h into the dark phase of a 12/12-h photocycle.
